**Abstract**: The purpose of this study was to evaluate the effect of manual lymph drainage (MLD) on postoperative edema recovery after orthognatic surgery performed under Vodder's technique. A total of 50 patients were divided into two groups: the first group received MLD treatment postoperatively, while the second group did not receive the treatment. The results showed statistically significant differences between the two groups in terms of edema recovery, with the MLD group recovering more quickly. This study highlights the potential benefits of MLD in facilitating the recovery process after orthognatic surgery.
