Abstract:
This study aimed to investigate the epidemiological, clinical, and paraclinical features of registered cases of tuberculosis in Ghaemshahr during the years 2010-2017. The study was conducted by collecting data from the tuberculosis registry of the Ghaemshahr Health Center. The data were analyzed using descriptive and inferential statistics. The findings showed that the incidence of tuberculosis was highest among the elderly, followed by the adult population. The majority of the cases were diagnosed in the respiratory tract, with the lungs being the most common site of involvement. The study also highlighted the need for continued surveillance and early detection of tuberculosis cases to prevent the spread of the disease.
