**Abstract:**
Gender-based variability has been observed in the presentation of pemphigus vulgaris, a chronic autoimmune bullous disease characterized by the formation of autoantibodies directed against the epidermal basement membrane. This study aimed to evaluate the gender-based variability in disease presentation in pemphigus vulgaris during March 2015- March 2018. A total of 100 patients with pemphigus vulgaris were retrospectively enrolled in this study. The patients were divided into two groups: men and women. The study findings showed that women had a higher incidence of oral involvement and a lower incidence of signs and symptoms of dermatologic involvement. This study suggests that gender-based variability should be considered in the management of pemphigus vulgaris.
